Clustering is always

Clustering is hard!

7

Clustering is fuzzy

8

Similar objects should be assigned the same cluster

Dissimilar objects should end up in different clusters

Clusters aren't pre-defined

Prof. Dr. Mirco Schönfeld | Data Modeling & Knowledge Generation | v1.0

Clusters should have a few geometric characteristics:

- Connected \bullet
- Separated \bullet
- Low variance \bullet
- Higher density than surrounding

Why is it hard and fuzzy?

Many applications involve several hundred or several thousand dimensions

- High-dimensional spaces look different (Pairs of points are hard to distinguish)
- No precise definition of "clusters"
- No precise definition of "validity" of clusters
- Subjective results, no specific definition seems "best" in the general case

Clustering Problems

Marketing: discover groups of purchasing activities

Climate: patterns of atmospheric phenomena help understand Earth climate

Economics: market research

Information Science: Clustering documents according to their topic

Requirements for Clustering

A dataset which is a collection of *points* which belong to some space which allows to measure *distance*.

Points in Euclidean Space

12

Clustering performs best in low-dimensional Euclidean spaces:

- Every point is a vector of real numbers
- The length of the vector is the number of dimensions
- Components of vector are coordinates of points

chihuahua 3: <2.53, 21.2> 🗲 Weight: 2.53 kg Height: 21.20 cm

Leskovec, J., Rajaraman, A. and Ullman, J.D., 2020. *Mining of massive data sets*. Cambridge university press. https://en.wikipedia.org/wiki/File:Chihuahua1 bvdb.jpg

Points in Non-Euclidean Space

Example: a text document is described by occurring words

The "space" consists of all axes describing all words of a dictionary (i.e. the set of selected words)

- One axis represents one word, values of 0 or 1 only indicating the presence of a word

"The internet is a network of computers. In this network, a lot of data is transmitted." Vector representation: <0,1,0,0,1,0,0,1>

- Words:
- 1. Social
- 2. Network
- 3. Computer
- Media
- Internet
- 6. Meme
- 7. Machine
- 8. Learning
- 9. Data

Measuring Distance

A distance measure is a function d(x, y) that produces a real number, to which arguments x and y are points in space

Important properties:

14

• No negative distances:

Zero-distances only for the distance from a point to itself

Distances are symmetric lacksquare

• Triangle inequality

- $d(x, y) \geq 0$ d(x, y) = 0 if and only if x = y
 - d(x, y) = d(y, x)
 - $d(x, y) \le d(x, z) + d(z, y)$

Well-Known Distance Metrics

15

Schöch, Christof. "Quantitative Analyse." Digital Humanities. JB Metzler, Stuttgart, 2017. 279-298.

Euclidean space:

- Euclidean distance
- Mahalanobis distance
- Manhattan distance
- Cosine distance

Non-Euclidean space:

- Jaccard distance
- Hamming distance
- Gower's distance

More Distance Metrics

There are a lot more distances!

Every data type needs their own distance metric, for example:

- distances between geographic coordinates
- distances between text documents
- distances between graphs or nodes in graphs

Strategies of Clustering

17

Hierarchical Agglomerative Clustering

Each point is in its own cluster

Clusters are combined based on their "closeness"

Combination stops when undesirable clusters occur

Leskovec, J., Rajaraman, A. and Ullman, J.D., 2020. *Mining of massive data sets*. Cambridge university press.

Point assignment

Initial clusters are estimated

Points are considered in some order

Points are assigned to clusters into which they best fit

Examples: Hierarchical Clustering

WHILE more than one cluster left DO

END

- pick the best two clusters to merge
- combine those two clusters into one cluster

Examples: Hierarchical Clustering

WHILE more than one cluster left DO

END

How will clusters be represented? How will we choose which clusters to merge?

- pick the best two clusters to merge
- combine those two clusters into one cluster

This is the agglomerative approach (bottom up). A divisive approach exists as well which starts with one cluster that is recursively split

Hierarchical Clustering: Represent Clusters

We need to combine nearest/closest clusters.

Key question: how to represent the "location" of each cluster to tell which pair of clusters is closest?

In Euclidean spaces: each cluster has an average of its points – the centroid

In Non-Euclidean spaces:

Only "locations" are the points themselves We do not have an average of points Choose a **clustroid** which is a point closest to other points

Centroids and Clustroids

Cluster on 3 points (Data)Point Centroid The average of all points in the cluster. It is an **artificial** point.

Clustroid An **existing** point that is closest to all other points in the cluster.

Determining the clustroid, i.e. the point being closest to all other points: Point with smallest maximum distance to other points Point with smallest average distance to other points More complicated notions

Hierarchical Clustering: Compare Clusters

22

Single-linkage:

Minimum distance (roughly maximum similarity)

Complete-linkage:

Maximum distance (roughly minimum similarity)

Average-linkage:

Average distance

Centroid-linkage:

Distance between cluster centroids.

Only for Euclidean spaces.

Hierarchical Clustering: Compare Clusters

23

Min-Max-linkage:

Best maximum distance (best minimum similarity)

Ward-linkage:

Minimum increase of squared error

McQuitty (WPGMA):

Average distance to the previous two clusters. Recursive definition

Median-linkage:

Distance between cluster midpoints. Recursive definition

From Dendrograms to Clusters

24

Hierarchical clustering outputs a dendrogram, but not "clusters"

Various strategies to select a clustering:

- Choose visually interesting branches
- Cut tree horizontally
- Other scientific approaches using \bullet cluster distances, densities, sizes, clustered objects,

Questions:

- Are clusters allowed to overlap? \bullet
 - How to handle outliers?

Hierarchical Clustering: why and why not?

Pro:

25

- Very general. Supports any distance metric
- Number of clusters doesn't need to be known beforehand

Contra:

- Unbalanced cluster sizes
- Outliers
- Slow for large datasets

Place each point in the cluster whose current centroid is the nearest WHILE points are moving between clusters and centroids not stabilized DO

Update locations of centroids of k clusters Reassign all points to their closest centroid

END

Disclaimer:

This is the standard k-means algorithm proposed by Lloyd (1982) It is, however, not the most efficient variant.

Clusters represented by their arithmetic mean

Optimizes "least squared errors", i.e. minimizes distance of points from centroids

That's why k-means is bound to Euclidean distance in Euclidean spaces

28

29

How to choose k: Elbow Criterion

36

Rousseeuw, P. J. (1987). Silhouettes: a graphical aid to the interpretation and validation of cluster analysis. Journal of computational and applied mathematics, 20, 53-65.

Assessing Quality of Clustering

Meaningful clusters are highly subjective

Also, data is never exact or complete

Optimal results are maybe not the most useful

Modeling Decisions

39

No single "best" setting for the general case

Expert decisions required on

- Feature selection
- The choice of clustering algorithm
- Parameters of algorithm
- Preprocessing and optimization techniques applied to data
- Distance measure suitable for the scenario
- Cluster quality criterion

Every configuration might yield different results!

Feature Selection

Describing objects is a careful process called *feature selection*

Producing redundancy in features should be avoided!

- Information needs to be selected that describe the objects best for the task of interest

Feature Selection

Formulate characteristics that help distinguishing objects. For spam-detection: find words or combinations of words that indicate a mail being spam.

Hey Peter, It was good to hear from you. ... Ham: PDS implies convexity of the resulting optimization problem (Kernel Ridge ...

Curse of Dimensionality:

Including more features will improve classification conceptually but will render computation increasingly difficult.

Curse of Dimensionality

In high-dimensional spaces

42

- ...almost all pairs of points are equally far away from one another
- ...almost any two vectors are almost orthogonal

Variance in distances shrink

Normalization and Standardization

Normalizing variables means mapping values into a new interval, usually [0,1]

- $x'_i = \frac{x}{\max}$
- Standardizing variables means to transform values to z-scores indicating divergence from mean (unit: standard variance)
 - $x'_i =$
- Often required to be able to compare features. Other (non-linear) transformations possible – e.g. to deal with skewness of variables
- Normalized features matter "the same amount"

$$x_i - \min(X_i)$$

$$x(X_i) - \min(X_i)$$

$$\frac{x_i - \mu(X_i)}{\sigma(X_i)}$$

 $\mu(X_i)$ is the arithmetic mean of variable X_i $\sigma(X_i)$ is the standard deviation of variable X_i

Normalization and Standardization

Standardized data:

Scaling

Scaling means to transform values of certain features

certain features (weighting)

Suppose some data with 2 features

Multiplying the second feature by 2 influences the distance to other points

Scaling effects distances between points, i.e. it allows to influence the "relevance" of

When to scale?

Name	Age	Weight (kg)	Weight (Ibs)
Α	25	80	176.37
В	25	90	198.42
С	30	80	176.37
D	30	90	198.42
